**TP 3.4**

Margin of error based on distance and cut angle

Assume: \( d >> R \)

From the bottom right portion of the figure above, equating the vertical components of the loop (perpendicular to the horizontal project line) gives:

\[
d \cdot \sin(\Delta \phi) = 2 \cdot R \cdot \sin(\Delta \theta - \phi + \Delta \phi) + 2 \cdot R \cdot \sin(\phi - \Delta \phi)
\]
Therefore,

\[
\Delta \theta(d, \phi, \Delta \phi) := \phi - \Delta \phi + \text{asin} \left( \frac{d}{2R} \cdot \sin(\Delta \phi) - \sin(\phi - \Delta \phi) \right)
\]

The following plot shows how the angular error in OB motion ($\Delta \theta$) varies with distance between the CB and OB ($d$) at different cut angles ($\phi$) for a given angular margin for error ($\Delta \phi$) in CB motion (1 deg):

\[
d := 0, 0.1, 0.48
\]

The following plot shows how the angular error in OB motion ($\Delta \theta$) varies with CB angle margin for error ($\Delta \phi$) at different distances between the CB and OB ($d$) for a 1/2-ball hit (30 deg cut angle):

\[
\Delta \phi := 0, 0.1, 0.2, \text{deg}
\]
Example: What is the allowable object ball (OB) angle error and required cue ball (CB) angle accuracy for a slow, 30-degree cut angle (half-ball hit) shot straight into a corner pocket (i.e., the angle to the pocket is 0 degrees) if the distances between the CB and OB and the OB and pocket are both about 4 diamonds (about 4.5’ = 54” on a 9’ table)?

From Figure 3.41 in the book, the approximate allowable object ball angle error is:

\[
\Delta \theta_{\text{allowable}} := 2 \text{deg}
\]

The distance between the CB and OB is:

\[
d := 54
\]

and the cut angle for a half-ball hit is:

\[
\phi := 30 \text{deg}
\]

Therefore, the required cue ball angle accuracy is:

initial guess: \(\Delta \phi_{\text{required}} := 0.1 \text{deg}\)

Given

\[
\Delta \theta(d, \phi, \Delta \phi_{\text{required}}) = \Delta \theta_{\text{allowable}}
\]

Find(\(\Delta \phi_{\text{required}}\)) = 0.073 deg

So the margin for error for the CB in this shot is very small (less than 0.1 degree!)
Allowable cue ball margin for error for various cut angles for the example shot above:

\[ \Delta \phi := 0.01\text{-deg} \quad \text{initial guess} \]

\[ \Delta \phi_{\text{required}}(\phi) := \text{root}(\Delta \theta(d, \phi, \Delta \phi) - \Delta \theta_{\text{allowable}}, \Delta \phi) \]

\[ \phi = 0\text{-deg}, 1\text{-deg}, 90\text{-deg} \]

\[ \Delta \phi_{\text{required}}(0\text{-deg}) = 0.083\text{ deg} \]

\[ \Delta \phi_{\text{required}}(30\text{-deg}) = 0.073\text{ deg} \]

\[ \Delta \phi_{\text{required}}(60\text{-deg}) = 0.043\text{ deg} \]

\[ \frac{\Delta \phi_{\text{required}}(0\text{-deg})}{\Delta \phi_{\text{required}}(30\text{-deg})} = 1.142 \quad \text{a straight-in shot is 1.15X (15%) easier than a 30 degree cut angle shot.} \]

\[ \frac{\Delta \phi_{\text{required}}(0\text{-deg})}{\Delta \phi_{\text{required}}(60\text{-deg})} = 1.939 \quad \text{a straight-in shot is 1.97X (97%) easier than a 60 degree cut angle shot.} \]
NOTE - If the effective size of the pocket (s) is known (e.g., from TP 3.5-3.8), the allowable angular error in the OB direction (\(\Delta \theta\)), for a given distance to the pocket (\(d_p\)), can be calculated with:

\[
\Delta \theta = 2 \cdot \tan^{-1} \left( \frac{s}{2d_p} \right)
\]

A simple way to estimate the effective size of a pocket is to subtract 2 inches (a little less than a ball diameter) from the point-to-point pocket-size measurement (p). For example, for the shot above, with a 4.5" pocket, with the OB 4.5 feet from the pocket:

\[
p := 4.5\text{ in} \quad d_p := 4.5\text{ ft} \\
s_{\text{approx}} := p - 2\text{ in} = 2.5\text{ in} \\
\Delta \theta_{\text{approx}} := 2 \cdot \tan^{-1} \left( \frac{s_{\text{approx}}}{2d_p} \right) = 2.7 \text{ deg}
\]
