$m_b := 6 \cdot oz$	ball mass
$m_s\!\coloneqq\!19\boldsymbol{\cdot}\boldsymbol{oz}$	typical cue mass
$m_{rack} \coloneqq \frac{3}{2} \cdot m_b$	effective mass of a rack of balls from: http://billiards.colostate.edu/high_speed_videos/new/HSVB-45.htm
$v_b \coloneqq 30 \cdot mph$	ball speed after impact (for a ver-fast-speed break shot)
$\Delta t_{tip} \coloneqq 0.0008 \cdot s$	typical tip-ball contact time (with a hard tip at fast speed) from: http://billiards.colostate.edu/threads/cue_tip.html#contact
$\varDelta t_{ball}\!\coloneqq\!0.00025 \!\cdot\! s$	typical ball-ball contact time from: http://billiards.colostate.edu/threads/balls.html#contact

The average CB speed during tip contact is:

$$v_{b_avg} \coloneqq \frac{v_b}{2} = 15 mph$$

Therefore, the distance the CB (and tip) travels while the tip is in contact is:

 $\Delta x \coloneqq v_{b_a a v g} \cdot \Delta t_{tip} = 0.211 \ in \qquad \Delta x = 5.364 \ mm$

The momentum of the CB is created by the impulse between the tip and CB. Assuming a triangular and symmetric impulse-force profile (at peak force F_{peak}):

$$\frac{1}{2} \boldsymbol{\cdot} F_{peak} \boldsymbol{\cdot} \Delta t_{tip} = m_b \boldsymbol{\cdot} v_b$$

So the peak force between the tip and CB is:

$$F_{peak} \coloneqq \frac{2 \cdot m_b \cdot v_b}{\Delta t_{tip}} = 1282 \ lbf$$

This corresponds to a peak acceleration (in units of g):

$$a_{peak} \coloneqq \frac{F_{peak}}{m_b} = 3419 \ g$$

When the CB hits the rack of balls and bounces back (with speed $v_{b'}$), both momentum and energy are conserved (assuming a perfect collision):

 $m_b \cdot v_b = m_{rack} \cdot v_{rack} - m_b \cdot v_{b'}$

$$\frac{1}{2} \cdot m_b \cdot v_b{}^2 = \frac{1}{2} \cdot m_b \cdot v_{b'}{}^2 + \frac{1}{2} \cdot m_{rack} \cdot v_{rack}{}^2$$

Re-writing and solving these equations for $v_{b'}$ gives:

$$v_{b} = \frac{3}{2} \cdot v_{rack} - v_{b'}$$

$$v_{b}^{2} = v_{b'}^{2} + \frac{3}{2} \cdot v_{rack}^{2}$$

$$= v_{b'}^{2} + \frac{2}{2} \cdot (v_{b'} + v_{b'})^{2} \xrightarrow{solve, v_{b'}} [-6 \cdot n]$$

$$\left(v_{b}^{2} = v_{b'}^{2} + \frac{2}{3} \cdot \left(v_{b} + v_{b'}\right)^{2}\right) \xrightarrow{solve, v_{b'}} \begin{bmatrix} 6 \cdot mph \\ -30 \cdot mph \end{bmatrix}$$

 $v_{b'} = 5 \cdot mph$

The impulse between the CB and the rack is equal to the change in momentum of the CB:

$$\frac{1}{2} \cdot F_{peak} \cdot \Delta t_{ball} = m_b \cdot \left(v_b + v_{b'} \right)$$

So the peak force between the CB and rack is:

$$F_{peak} \coloneqq \frac{2 \cdot m_b \cdot \left(v_b + v_{b'}\right)}{\Delta t_{ball}} = 4786 \ lbf$$

This corresponds to a peak acceleration (in units of g) of:

$$a_{peak} \coloneqq \frac{F_{peak}}{m_b} = 12764 \ \mathbf{g}$$
